Contents	~~~~~	Page 49

3D Workset Views

Tooltip: Create 3D workset checking view in your working folder.
Each workset will get a 3D view that only have this workset turned on.

If there are no 'Views_\$Group' and 'Views_\$Series' in the view parameter, such as the case in using other firm file setup, the tool will not introduce 'Views_\$Group' and 'Views_\$Series' to them, the new 3D workset views will be just using revit default '???' group.

Amazing Auto Export

Tooltip: Export a scheduled set of sheets to PDF, DWG, and JPG without anyone at the keyboard.

The workhorse behind the firm's overnight exports. It opens the cloud model on its own, produces the sheet set in each requested format, drops the files in the agreed project folder, tells the team the run is done, and closes Revit behind itself.

Features:

- PDF, DWG, and JPG produced in one pass over the sheet set
- Runs unattended on a schedule, so the model is fresh each morning
- A notification goes out when the export finishes or fails

Batch Format Family Name

Tooltip: Batch rename family names to the Healthcare standard convention.

Format: CATEGORY_MainDescription_FIRM[_AdditionalInfo][_HOSTING]

Edit the components inline in the grid, check the families to fix, and Apply. Analysis and naming-rules helpers are one click away.

Change Family Category

Tooltip: Batch change family categories with user-friendly interface and comprehensive reporting.

Check Linked-View Relationship

Tooltip: Report which views depend on which, so you know what breaks before you delete one.

Views quietly reference each other through dependents and callouts. This lists every one of those relationships, so you can see why a view is showing something you did not expect, and what would go with it if you deleted it.

Features:

- Circular references between views are called out
- Nothing in the model is changed; this is a read-only check

Check Phase Mapping

Tooltip: Get the phase mapping of multiple documents.

CleanUp Family

Tooltip: Slim down the families you pick by purging what is unused inside them.

Bloated families make a model slow to open and heavy to sync. This opens each family you select, throws out the unused types, materials, and imports hiding inside, then reloads the lighter version into the project.

Features:

- Nested families are cleaned too, all the way down
- Optionally set every cleaned family to consistent metric or imperial units
- A summary reports what came out of each family

Usage:

1. Run the button and tick the families to clean
2. Choose whether to standardize units
3. Review the summary when the reload finishes

Collect Textures

Tooltip: Gather every material texture image into one folder and repoint the materials at it.

Renderers break when texture images live on someone's desktop. This copies the image behind each material into a shared folder and updates the material to point at the new copy, so the model renders the same on any machine.

Features:

- Runs across every material in the model
- A progress bar shows the material being processed, and can be cancelled
- The whole repoint is one undo step

ColorScheme To FilledRegion Types

Tooltip: Turn a color scheme into filled region types so diagrams match your plan colors.

Pick a color scheme and every entry in it becomes a filled region type carrying that entry's exact color, ready to draw with. Existing types are refreshed rather than duplicated, so re-running after a color change keeps your diagrams in step with the plans.

Features:

- Each type is named after its scheme entry so it is easy to find in the type list
- The whole conversion is one undo step

Usage:

1. Run the button and pick the color scheme to convert

ColorScheme2Excel

Tooltip: Export any color scheme to Excel so the colors can be edited outside Revit.

Every entry in the scheme lands in a spreadsheet with its color, ready to hand to a consultant or mark up yourself. Bring the edits back with Excel2ColorScheme.

Features:

- Export several schemes at once, each on its own worksheet
- Choose whether to include entries that no element currently uses
- The model is not changed; this only writes a spreadsheet

Usage:

1. Run the button and tick the schemes to export
2. Say whether unused colors should be included

Create Sheets By Excel

Tooltip: Create new sheets based on data from Excel.

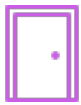

If you need help on what kind of Excel to prepare, you can open a sample excel and begin from there.

Create Worksets

Tooltip: Create Worksets following the standard Ennead Workset Structure.

You can the options to create any or all from below:

Door Calc Pt Visualizer

Tooltip: Draw detail lines from each door to its room calculation points in the views you pick.

Makes it obvious which rooms a door is reporting to and from, so doors that feed the wrong room in a schedule stand out instead of hiding in the numbers.

Features:

- Blue lines run to the To Room, red lines run to the From Room
- Doors that carry no calculation points are counted and skipped
- Summary of processed doors printed when it finishes

Duplicate Area Scheme

Tooltip: Duplicates a Revit area scheme to a new area scheme with all boundaries and areas.

This tool allows you to:

1. Select an existing area scheme to duplicate
2. Provide a new unique name for the duplicated scheme
3. Choose which views to include in the duplication process
4. Automatically transfer all boundaries and areas to the new scheme

Excel2ColorScheme

Tooltip: Push colors edited in Excel back into a Revit color scheme.

Edit your colors where it is comfortable, then bring them back in one step. Two workflows are supported and the button asks which one your spreadsheet came from.

Features:

- Round-trip: for a spreadsheet you exported with ColorScheme2Excel, one scheme per file
- Office template: for the standard Ennead sheet with Department and Program columns side by side, which updates both schemes in one pass
- Online: no Excel needed - pull the project's color book straight from enneadtab.com (Department + Program), applied in one pass. Sign in once when prompted.

Usage:

1. Run the button and pick the source (Excel round-trip, Excel office template, or Online)
2. For Excel: pick the file and scheme. For Online: enter the project number and sector.

Export Filled Region Types

Tooltip: Export the filled region color setting to excel so you can use it elsewhere.

Family RePath

Tooltip: Save the project's families out to a folder of your choice, sorted by category.

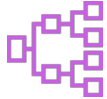

Pulls the families you pick out of the model, files them into category subfolders in the folder you name, and loads the tidied copies back into the model. The result is one clean, findable family library instead of paths scattered across desktops.

Features:

- Families are grouped into subfolders by their Revit category
- Optionally reach into nested families and save those out too
- Optionally sync and close the model when the reload is done, so you can walk away

Usage:

1. Run the button and tick the families to save out
2. Pick the destination folder
3. Choose whether to include nested families and whether to sync and close afterwards

Family Tree

Tooltip: See what is nested inside your families as an interactive tree in your browser.

Draws the whole parent and child chain of a family so you can finally see what is buried inside it, and click any node to read its parameters. Handy before cleaning or repathing a family you did not build.

Features:

- Works from a project or from inside an open family
- Click through the tree to expand and collapse each level
- Nothing in the model is changed; the tree is only a view of it

Get Model GUIDs

Tooltip: Read out the cloud identifiers of the open model so it can be added to Auto Export.

Setting a model up for overnight export needs two identifiers that Revit does not show anywhere in its interface. Run this from the open cloud model and both are printed, ready to copy into the Auto Export setup.

Features:

- The cloud region is reported alongside the identifiers
- You are told plainly if the open model is not a cloud model
- Nothing in the model is changed

Inspect Excel Formula

Tooltip: Reveal the hidden formulas in a spreadsheet before you trust its numbers.

A cell that looks like a plain number may be a formula pointing somewhere else. This lists every formula in the worksheet you pick and marks those cells with a dashed border in a local copy, so you can see at a glance which numbers are calculated and which were typed. Worth doing before importing consultant data into Revit.

Features:

- Your original spreadsheet is not modified; the marked-up copy is a separate file
- Every formula is printed to the output window

Usage:

1. Run the button and pick the Excel file
2. Pick the worksheet to inspect

Inspect Local Graphic Override

Tooltip: Find the views where someone has overridden graphics by hand instead of by template.

Local overrides and hand-hidden elements are invisible until a drawing prints wrong. This walks the views on the sheets you pick and reports every override and hidden element that the view template does not control, so you can put the view back under template control.

Features:

- Read the findings in Revit, or export them for review in Excel
- Nothing in the model is changed; this is a read-only audit

Usage:

1. Run the button and pick the sheets whose views you want checked
2. Choose whether to review in Revit or export the list

Keynote Assistant

Tooltip: Manage the whole project keynote list from one searchable window.

Add, edit, and reorganize keynotes without hunting through the keynote text file. Search the whole list, move keynotes between categories, and edit many at once instead of one at a time.

Features:

- Search across every keynote in the project
- Reorganize keynotes into categories by dragging
- Edit or retire a batch of keynotes in one go
- Translate keynote text for international project teams

Legend&Schedule; Where?

Tooltip: Which Legend and Schedule were used? Where are they?

If you have been wondering about those question, this tool can help you with it.

It list all the current locations for the schedules and legend, with a clickable link!

Lines-In-View Locator

Tooltip: Rank the views hoarding the most drafting and model lines, worst offenders first.

A model that has grown slow is usually carrying a few views stuffed with hand-drawn lines. This counts them and ranks the views, so you know exactly where to go and what to clean up.

Features:

- Detail lines and model lines are reported separately
- Each line's workset is listed so you can trace who owns the mess
- Nothing in the model is changed; this is a read-only report

Links2Worksets

Tooltip: Convert each revit link into its own workset.

List Families

Tooltip: Lists selected families in organized views.

This script allows listing of both 2D detail items and 3D families in dedicated views. Detail items are placed in a drafting view while 3D families can be placed in either a 3D view or floor plan view. Families are organized by category with labels and optional tags.

Key Features:

- Supports both 2D detail items and 3D families
- Organizes families by category with clear labeling
- Creates dedicated views for family display
- Optional tagging support
- Handles hosted families with appropriate host elements
- Creates category-specific filtered views

Note:

3D families will be visible in all project views. The script creates an internal level far from the main project levels to minimize interference.

Merge Object Style

Tooltip: Merge duplicate object styles (subcategories) into a single target.

Solves the 'boomerang' problem where deleted subcategories reappear because families still carry them internally.

Workflow:

1. Pick the bad subcategory to remove and the target to keep.
2. Dry-delete the bad subcategory (rolled back) to discover every family and project element that references it.
3. Open each affected family (loadable and in-place), reassign geometry from bad to target subcategory, delete the bad one, and load the family back.
4. Reassign project-level elements (detail lines, filled regions, etc.) and delete the bad subcategory from the project.

Note: Category.Name is read-only in the Revit API so subcategories cannot be renamed directly; elements must be reassigned instead.

Monitor Link Status

Tooltip: Monitor and compare grid and level elements between current document and linked documents. This tool helps track differences in grids and levels between the host document and its linked models. It identifies elements that exist in one document but not in others, and checks monitoring status.

Open Keynote Exporter

Tooltip: Open the Keynote Exporter -- now a standalone web service.

The Keynote Exporter has been extracted from EnneadTab-OS into its own product at <https://enneadtab.com/keynote-exporter>. This button opens it in your browser; the old bundled .exe was retired to shrink the repo. Revit stays open and your model is untouched.

Open Sample Excel

Tooltip: Get a sample excel to fill out data in similar format.

Using those format will make it easy to generate dummy sheets in Revit.

Please note that Chinese translation will require special care when saving excel format.

Project Initiating

Tooltip: Set up a brand new project in one window instead of a dozen separate dialogs.

Everything you normally do by hand on day one of a model, gathered in one place. The window stays open beside the model so you can work through the setup at your own pace.

Features:

- Create the office standard worksets in one click
- Build levels from a grid you fill in
- Create the whole sheet set from a spreadsheet
- Fill in the project information fields quickly

Property Line From Excel

Tooltip: Generate detail line from the Excel survey pt data. Best used for property line generation.

QAQC Reporter

Tooltip: Produce a health report on the model and ask questions about it in plain English.

Runs the firm's quality checks over the open model and gathers the results into one report. Instead of scrolling it, you can just ask: what are the critical issues, is this model ready to issue, which worksets are a mess. Good before a milestone or a coordination review.

Features:

- Ask follow-up questions in plain English and get answers from the report
- The window stays open beside the model so you can fix issues as you read
- Nothing in the model is changed; this is a read-only review

Relationship Diagram

Tooltip: Interactive canvas to draw relationship diagram.

Rename Nesting Family

Tooltip: Strip the conflicting-name tag Revit leaves on nested families after a bad load.

When two families collide on load, Revit quietly renames the nested one and leaves an ugly marker in its name. This finds every nested family carrying that marker, cleans the name back up, and reloads the corrected family into the project.

Features:

- Every family in the project is checked, including the ones nested inside them
- Families you cannot edit are skipped
- A log lists every rename that was made

Usage:

1. Run the button and let it work through the families
2. Review the list of renames in the output window

Rename Parameters

Tooltip: Rename family parameters without losing the values already set in the project.

Renaming a parameter by hand normally wipes whatever every instance had in it. This carries the values across, so schedules, tags, and filters keep reading the same numbers under the new name.

Features:

- Rename several parameters in one pass from a single dialog
- The dialog stays open so you can keep working in the model beside it
- Values are read back and re-applied after the rename

Usage:

1. Run the button and pick the family to work on
2. Type the new name beside each parameter you want changed
3. Apply, and check the values survived in a schedule

Repath Dwg Drive Letter

Tooltip: Pick the old and new drive letters to repath all linked DWGs.

Report Last Crash

Tooltip: Upload the most recent closed Revit journal to Crash Detective and open the diagnosis.

Finds the latest closed-session journal under %LOCALAPPDATA%\Autodesk\Revit, asks for confirm, then submits it for automatic analysis and opens the investigation result page. If upload is not possible (file too large, network, or API unavailable), copies the journal path to the clipboard and opens the Crash Detective site so you can drop the file manually.

Features:

- Prefers the prior closed session over the live Revit journal when distinguishable
- Confirm dialog before any upload (Cancel does nothing)
- Graceful clipboard fallback when the journal is oversized or upload fails
- Works with no document open (zero-doc)

Revision Cloud Color Manager

Tooltip: Give each revision its own cloud color so revisions read apart at a glance.

Every revision cloud in the model looks the same until you color them. This assigns a distinct color per revision, so a sheet carrying three revisions tells its own story.

Features:

- A ready-made color palette, or pick your own color per revision
- Turn the coloring on for review and off again before issue
- Your color choices are remembered and reused on the next model

Usage:

1. Run the button and set a color against each revision
2. Turn coloring on to review, and off when you are done

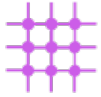

Smart Egress Path

Tooltip: Draw egress paths whose travel distance and tags update themselves as the plan changes.

Each path is placed as a tagged marker with its travel distance read straight off the geometry, so when a wall moves the distance on the drawing moves with it. No more re-measuring routes by hand every time the plan shifts.

Features:

- The path marker and tag families are loaded for you if they are missing
- An egress path schedule is created so every route can be checked in one table
- Distances stay correct as the design evolves, ready for the code review

Smart Match Grid Extend

Tooltip: Match grid bubbles and extents across every plan to a reference view you nominate.

Grid bubbles drift out of step view by view until no two plans agree. Pick the view that is right, and every other floor plan and area plan is brought into line: the same bubbles shown, the same ends hidden, the same extents.

Features:

- Covers every floor plan and area plan in the model
- Each grid end is matched independently, so half-shown grids stay half-shown
- The whole match is one undo step

Usage:

1. Run the button and nominate the reference view whose grids are correct
2. Let it work through the remaining plans

Transfer Color Scheme

Tooltip: Copy every entry, color, and fill pattern from one color scheme onto another.

Saves rebuilding a scheme by hand when a second one needs to look the same. Entries missing from the destination are added; where an entry already exists you are asked before its color is overwritten.

Features:

- The two schemes must cover the same category, and you are told if they do not
- A summary lists what was added and what was overwritten
- The transfer is one undo step

Usage:

1. Run the button and pick the scheme to copy from, then the one to copy onto

Transfer Parameter Data

Tooltip: Transfer some data from one parameter to another.

When you inherited from older file some parameter is carried over and now you have duplicated parameter container. Use this to cleanup the parameter panel

Update DOB Page Number

Tooltip: For DOB submission in NYC there requires a page number on the titleblock.

View Reference Tree

Tooltip: Map how your sheets and views reference each other, and open the map to explore.

Follows every callout, section, and elevation marker to build a picture of which view points at which. Use it to find orphan views, trace where a detail is called up from, or see the shape of the drawing set before an issue.

Features:

- Covers every sheet and every view placed on them
- Nothing in the model is changed; the map is only a view of it

Wall Type Diagram

Tooltip: Create a wall type legend and matching view filters, one color per wall type.

Each wall type takes its color from the filled region type already associated with it; when there is none, a fresh color is picked for you. The filters can be pushed onto a view template so every plan reads the same way.

Features:

- Legend view with a color box and label for each selected wall type
- One view filter per wall type, with a consistent color override
- Optional apply to a view template you choose

AR/VR Overlay

Tooltip: Open EnneadTab-ARVR: Mobile Camera AR Overlay for 3D Models.

Beam an already-exported 3D model onto your smartphone camera in augmented reality:

- Auto-detect a staged .glb matching the active 3D view, or browse to pick an existing .glb / .gltf / .usdz you exported some other way
- Staged safely in local temporary dump directory
- Upload directly into cloud room session
- Scan QR code to launch mobile camera AR overlay with 1:1 scale
- Zero app installs needed on phone or headset

Note: this tool does not export the Revit 3D view itself (Revit has no native glTF/GLB exporter). Export your model to .glb/.gltf/.usdz first, then use this tool to stage & beam it.

Opens <https://enneadtab.com/arvr>

Apply DOH SheetNum

Tooltip: Toggle live sheet numbers between the firm Internal scheme and the client DOH scheme.

Both schemes are stored permanently, so nothing is lost when you switch.
Applying a scheme copies the stored numbers into the live sheet number slot.

BigRhino2Revit(For Large Batch)

Tooltip: Convert recent Rhino2Revit output jobs into Revit families and load them into the project.

This tool processes all recent output jobs from Rhino2Revit in Rhino and:

1. Creates new generic families from template
2. Converts job files to Revit elements using filename as subcategory
3. Saves families to temp location and loads into main project
4. Moves newly loaded families to origin point

Block2Family

Tooltip: Converts Rhino blocks to Revit families.

This script processes block data exported from Rhino to create or update corresponding families in Revit.

Key features:

- Creates new families from Rhino block geometry
- Updates existing family instances
- Handles transformations (move/rotate) by removing old instances and creating new ones
- Preserves block parameters as family parameters
- Supports both UV projection (flat-modeled) and standing geometry
- Maintains Rhino block IDs for tracking

Input: .internal data files containing block data from Rhino

Output: Revit family instances with matching geometry and parameters

Brep2Mass

Tooltip: Rebuild breps exported from Rhino as native Revit mass geometry.

The shapes come back as real Revit forms you can host, schedule, and cut in section, instead of a dumb import you cannot work with.

Usage:

1. In Rhino, export the breps with EnneadTab for Rhino
2. Run this button and confirm the unit the Rhino file was drawn in

Content Transfer

Tooltip: Copy selected view templates, object styles, and materials between open models.

Unlike Transfer Project Standards, you choose exactly which items travel instead of swallowing a whole category. When a name already exists in the destination you can keep the destination version rather than overwrite it.

Usage:

1. Open both the source model and the destination model
2. Run the button, pick the source model, then tick the items to send
3. Review what transferred in the output window

DWG Export Update Layer

Tooltip: Randomize the layer color, and rename the layer to to format below:
Category_SubCategory

This tool does not change other existing setting for this export setting.
It makes life in Rhino easier after exporting contents over.

Ennead Exporter

Tooltip: A great helper for your print on deadline. Features include:

- pdf, dwg, jpg export together
- Package export files to subfolders in destination folder by assigned prefix and file type
- Prefix for auto numbering
- Email result as a link to folder.
- Time esitimation, with increasing accuracy the more you export
- Identify color setting per parameter on sheet. So you can mix color and BW export together.
- Option to sync and close files after exporting done.
- Export sheets by revision mark instead of printSet, and allow selective export without desrupting shared printSet.
- Export views on sheet seperatedly for dwg.
- Export from links or open docs.
- Merge pdf after export.
- JOKE while exporting.

Export SubCategory Material Table

Tooltip: Export the object style and material table so Rhino can match layers to materials.

Feeds the Map Revit SubC tool in EnneadTab for Rhino: once this table exists, each Rhino layer can be given the Revit material that belongs to the matching subcategory, and the two models finally agree on what is made of what.

If you have not done it yet, update the DWG export layer mapping with EnneadTab first, so subcategory names come out in a shape Rhino layer names can match.

Import Rhino Camera

Tooltip: Work with Camera exported in Rhino side to recreate the same perspective camera.

It can be useful for Enscape view recreation in Revit.

Import Rhino Material

Tooltip: Bring Rhino material definitions into Revit as new or refreshed Revit materials.

Materials that already exist in the project keep their identity and simply pick up the incoming color; the ones that are missing are created for you, so a Rhino model and a Revit model can be kept looking like the same building.

Usage:

1. Export the materials from Rhino with EnneadTab for Rhino
2. Run this button and review what was created versus updated

Isolated Export By System Family Type

Tooltip: Export a separate DWG file for each wall, floor, roof, column, or stair type.

Pick a category and the types you care about, and every type is isolated in the view and written to its own file. Child elements such as shared families ride along with their parent type.

Aimed at the system-family categories that are normally impossible to pull apart in a single DWG export. On the Rhino side, use Import Revit Export Collection to land each file under its own type parent layer.

Map Rhino Block to Revit Family

Tooltip: Place Revit families at the position and orientation of matching Rhino blocks.

Each Rhino block is matched to a Revit family type of the same name. The placed instance is no longer stuck being a level-based, vertical-up family: it can sit in any freeform orientation, exactly as it did in Rhino.

Usage:

1. Export the blocks from Rhino with EnneadTab for Rhino
2. Run this button and confirm the unit the Rhino file was drawn in
3. Blocks with no family type of the same name are listed in the output

Move2Origin

Tooltip: Move family instances to the internal origin while maintaining current orientation.

Three operation modes are available:

- 1: Family is placed in 3D view with incorrect location - Select it and move it.
- 2: Family is placed somewhere in 3D view but location unknown - Select from listbox and move it.
- 3: Family is newly loaded but not yet placed - Select from list and place at origin.

Note: Some element types have location constraints and may not be movable to absolute origin.
Report any issues to the EnneadTab team.

Publish to BimRunner

Tooltip: Publish selected sheets from the open model onto BimRunner's pinup wall.

Exports each picked sheet to PDF and uploads it to the current cloud model's project page on BimRunner, so a client or reviewer can see it without anyone emailing a PDF around. Republishing the same sheet later updates its existing entry instead of duplicating it, even if the sheet has since been renumbered.

The model is detected automatically from the open document -- there is nothing to search for or type. If the model has never been synced to BimRunner, or is not a cloud (ACC/BIM 360) model, publishing is blocked with a clear message instead of guessing.

Usage:

1. Open a cloud-workshared model already tracked in BimRunner
2. Run the button and click "Pick Sheets to Publish"
3. Click "Publish to BimRunner" and watch the per-sheet status
4. Review the pass/fail summary in the status window

Review On Miro

Tooltip: Push selected sheets to a Miro board and keep markup alive across sheet updates.

Because each sheet image is replaced in place, comments and redlines stay stuck to the drawing instead of being thrown away with the old PDF every time the background changes. Review history survives the whole set of revisions.

Features:

- Sheets new to the board are flagged with a blue cross
- Sheets whose background changed are flagged with an orange star
- The last board URL you used is remembered for next time

Revit2Rhino

Tooltip: Export the Revit elements of your choice to a Rhino file.

Pick the categories to export (walls, floors, windows, furniture, curtain panels...), then choose which family / type combinations to include. Each element is converted into a Rhino block instance placed at its original location, with the geometry (Breps, or Meshes as fallback) organized on layers by Category / Family / Subcategory.

Blocks are named after the family and type (a short suffix is added when the same type differs by parameters, or for system families such as walls). The export file name contains a timestamp, and Rhino opens when the export finishes.

Tip: Rhino.Inside must be running, and an architectural view (such as a 3D view) must be active. Only elements visible in the active view are listed. Elements from linked models are not exported.

Rhino Drafter

Tooltip: Draft curves and surfaces in Rhino and bring them into the current Revit view.

Curves arrive as detail lines and surfaces arrive as filled regions, so awkward 2D geometry can be shaped where it is easy to shape and finished where it needs to live. Rhino units are converted for you.

Features:

- Curves can also land as area boundary lines or room separation lines
- Works in plan views and in elevation views
- Round trip as many times as you need without retracing anything

Rhino2Revit(For Full Control)

Tooltip: Convert .3dm and .dwg files into native Revit family elements.

Compared to shape2family and block2family, this tool give you the maximal control over subCategory mapping to existing category so you revit will be the most clean.

Pair this usage with move2origin.

Key Features:

- Assign subcategories per file
- Add new subcategories on the fly
- Use source filename as subcategory
- Support major curve conversion (except NURBS curves with control points on different CPlanes)

Best used with EnneadTab for Rhino's Rhino2Revit exporter window.

Format Support:

.3dm Files:

- Stable conversion to native Revit elements
- Individual control of Boolean, Subcategory, Visibility, Dimensions
- Requires clean source models

.dwg Files:

- More tolerant of model imperfections
- Handles lines, arcs, circles and planar NURBS curves
- Elements from same source file are grouped
- Creates Import subcategories (auto-cleaned)

RoomOrArea2Diagram

Tooltip: Export Revit Rooms/Areas to Rhino as color-coded diagrams with XAML GUI.

This tool creates a simplified diagram representation of Rooms or Areas in Rhino:

- Exports boundaries with filleted corners and optional inner offset
- Maintains color coding from Revit color schemes
- Adds text labels for space identifiers
- Creates solid hatches for each space
- Features XAML GUI with persistent settings
- Supports both Rooms and Areas export
- Configurable corner fillet radius and inner offset distance
- Automatic settings save/restore for future use
- Framework ready for drafting view group export (future feature)

Schedule2Excel

Tooltip: Export and open schedule in excel.

Shape2Family

Tooltip: This is to handle all the incoming geometry made from Rhino's shape2revit command.

Srf2Adp

Tooltip: Turn surfaces drawn in Rhino into placed Revit adaptive components.

Pick the adaptive family and type to use, and each incoming surface is built from its corner points. Set the corner order in Rhino first so the adaptive points land where you expect them to.

Usage:

1. In Rhino, set the adaptive corner sequence and export the surfaces
2. Run this button, pick the family and type, and confirm the file unit

Change Family Unit

Tooltip: Convert between a typical imperial family and metric family by setting up unit.

CurtainWall Location Manager

Tooltip: Manage curtain wall locations by turning the walls in a plan into an abstract diagram.

The diagram gives you a clean line drawing to study and adjust curtain wall positions on. When the lines say what you want, run the tool again to push the locations back onto the real curtain walls.

Features:

- Left click processes the current view; right click processes views you select
- Edge of slab lines can be included when the floor type name contains "struc"
- Export the diagram views to images with Manage Working Views for quick review

DWG Manager

Tooltip: Find, review, and clean up every DWG in the model from one window.

Each imported or linked DWG is listed with who brought it in, which view it lives in, whether it is hidden, its workset, its path, and its file size, so a deliberate link is easy to tell apart from stray import junk.

Features:

- Select and zoom to any DWG in the model
- For linked DWGs, open the source file or its folder, or repath the link
- File sizes and paths shown, so heavy or missing links stand out

Family Parameter Batch Creation

Tooltip: Help you get started with many families by adding many useful parameter quickly.

Fire Rating Graphic

Tooltip: Fire Rating Graphic Manager

A comprehensive fire rating management system that streamlines code compliance documentation.

This powerful utility helps you:

- Assign and track fire ratings across wall types
- Generate intelligent graphics that update automatically across multiple views
- Maintain consistent fire separation documentation
- Ensure building code requirements are clearly communicated

Key Features:

- Intuitive UI for managing wall type fire ratings
- Batch updates across selected views
- Support for linked models
- Smart graphic family (Smart_Fire_Rating) with customizable appearance
- Real-time wall instance counting and preview

Perfect for maintaining consistent fire separation documentation and ensuring building code requirements are clearly communicated in your drawings.

Identify Wrong Type Of KeynoteTAG

Tooltip: Find keynote tags that use the wrong tag family or point at a user keynote.

A tag whose family or type name says material but that reads element keynote data is flagged, and the reverse case is flagged too. User keynotes, which the office standard steers away from, are called out separately.

Features:

- Mismatched tags are color overridden in the view they sit in
- User keynote tags are highlighted in blue
- Run KeynoteTAG Reset Color afterwards to clear all the highlights

Internal Annotation Handler

Tooltip: Handle internal textnotes and dimensions in the project.

This tool allows you to show or hide all internal textnotes and dimensions at once.

Filters elements by type names that begin with '_internal_note' prefix.

Works across all views including dependent views while respecting ownership permissions.

Isolate Warnings

Tooltip: Work through model warnings one by one in a window that zooms straight to each one.

Pick a warning and the model isolates and zooms to the elements causing it in a 3D view with a section box, so you can fix it where it lives instead of hunting for it. The warning count drops as you go, and syncing after the cleanup earns you EA coins.

Usage:

1. Run the button to open the warning window
2. Pick a warning to zoom to it, fix it, then move to the next
3. Sync when the list looks the way you want it

KeynoteTAG Reset Color

Tooltip: Clear the color overrides on every keynote tag so they draw in their default color.

Use this after the keynote checking tools, which color-code tags to flag problems. Tags or views owned by someone else in a workshared model are left alone and reported, so nothing is quietly half-reset.

Features:

- Sweeps every keynote tag in the model in a single undo step
- Count of reset and skipped tags shown when it finishes

Load Family From Link

Tooltip: Load families out of a linked Revit model without ever opening the link.

Pick the link, pick the families, and they land in the current model. In-place and system families cannot travel this way, so they are skipped and listed with the reason rather than failing quietly.

Usage:

1. Pick the linked model to pull from
2. Pick one or more families to load
3. Review the skipped list in the output window

Load Multiple Families To Multiple Docs

Tooltip: Pick many families, and load them to many projects. You can:

- 1 family >> x projects
- x families >> 1 projects
- x families >> x projects
- 1 family >> 1 project

Have bonus option to sync and close after done. And have option to pre-pick shared family loading behaviour. Handy for loading big family at end of day.

Manage Working Views

Tooltip: Review and clean up the views that are not on any sheet, all from one window.

Every unsheeted view is listed with a thumbnail, so you can judge at a glance whether it is someone's working view or dead weight. Delete the dead ones, or prefix names with their creator so ownership is obvious. Good housekeeping before a submission or a phase change.

Features:

- Thumbnail preview of each working view
- Filter the list by creator, view type, and name
- Batch rename with a creator prefix, or delete in bulk

Merge Family

Tooltip: Merge a few family types to a target family type:

For instance parameters, the tool tries to record as much information as it can, so after the merging, similar data can be applied back to maintain the graphical consistency.

There is a built-in check that will search for differences in type parameter data. Should differences be found, you will be prompted to decide to continue with merge or cancel.

If you find no ideal target type, you may also choose to create a new type under good family with the bad type data and type name.

This tool will work for most 2D and 3D families, as well as Tags.

Proj. Parameter Batch Adding

Tooltip: Batch adding shared parameters to multiple project files.
This can reduce mistake during manual operation of repeating task.

If this shared parameter has been added before, it will not add again.
Note that for Revit, the spelling is not important, the GUID is important.

Remove Not Placed Area and Rooms

Tooltip: Delete unplaced rooms and areas, and flag the ones that need a second look.

Anything not placed anywhere is deleted outright. Elements that are placed but unbounded or redundant are reported instead of deleted, because those are a design decision, not junk. Rooms are handled in the phase you pick; areas are handled across every phase.

Usage:

1. Pick the phase whose rooms you want cleaned
2. Review the deleted counts and the flagged list in the output window

Remove Revision From Sheets

Tooltip: Remove one or more revisions from many sheets at once.

Pick the revisions, then pick the sheets to strip them from. A revision that a sheet picked up from a revision cloud cannot be removed this way; those sheets are listed on their own at the end so you can go find the clouds.

Usage:

1. Pick the revisions to remove
2. Pick the target sheets
3. Check the output window for sheets still carrying a cloud-driven revision

Set Revision On Sheets

Tooltip: Add one or more revisions to many sheets at once.

Pick the revisions, then pick the sheets to stamp them on. Every sheet is updated in a single undo step, and each one is listed in the output window so you can confirm the issue went where you meant it to.

Usage:

1. Pick the revisions to add
2. Pick the target sheets
3. Review the updated sheets in the output window

Shake All Tags

Tooltip: Force every tag on the sheets you pick to redraw itself with current text.

Fixes blank or stale tag text without leaving any permanent change behind: each tag is nudged, the view refreshes, and the tag is put straight back where it was. The whole run is one undo step.

Features:

- Pinned tags are temporarily unpinned, then re-pinned
- Tags owned by another user in a workshared model are skipped
- Summary of shaken, refreshed, failed, and skipped tags when it finishes

Temporary Revision

Tooltip: Temporarily hide selected revisions (titleblock impact) and restore later.

Track Detail Group

Tooltip: Track down where detail groups are used, searching by view or by group.

The search runs in both directions: list every view a given detail group appears in, or list every detail group living inside the views or sheets you pick. Worth running before you edit a shared group, or when hunting content nobody uses.

Usage:

1. Choose a search direction when the dialog opens
2. Pick the views, the sheets, or the detail group to search on
3. Review the results in the output window

View Template Compare

Tooltip: Compare view templates side by side and get an interactive report of the differences.

Pick the templates and a table opens with one column per template and one row per setting that differs. Settings a template does not control are called out, since those are the ones that quietly let views drift apart.

Features:

- Category visibility and overrides: halftone, line weight, color, and the rest
- Workset visibility
- Filters in use and the overrides they apply
- View parameters, both the controlled ones and the ones left loose

WorkSet Manager

Tooltip: Move elements onto the workset they belong on, in bulk.

Say how each category should be assigned and the tool sweeps the model and reassigns everything sitting on the wrong workset. Elements inside design options are handled; elements inside groups are not, and are reported instead.

Features:

- Assign by category, by the host element's workset, or by element type
- Report of everything that could not be moved, and why

App Store

Tooltip: Open the EnneadTab App Store to browse and install extra tools.

Shows the curated catalog of EnneadTab utilities and add-ons, with installing and updating handled for you. Use it to pick up a tool you do not have yet, or to refresh one that has a newer version waiting.

Assistant

Tooltip: Your all-in-one resource center for EnneadTab and Revit mastery!

This comprehensive assistant provides quick access to:

- Learning resources and tutorials for Revit, Rhino, and CAD
- YouTube training playlists and Friday session recordings
- Family formula cheat sheets and reference guides
- Bug reporting and feedback submission tools
- Important Ennead and Autodesk websites
- Cache folder management to optimize C: drive space
- BIM360 GUID decoder to make sense of cryptic folder names
- Timesheet helper to track your daily activities
- Installation guides for other EnneadTab products

Perfect for both beginners and power users who want to maximize their productivity!

Beer Tab

Tooltip: Open a guide to the nearest places to get a beer.

A one-click break button for the end of a long modeling session. Opens a neighborhood beer guide in your browser. Nothing in the model is touched.

ChatGPT

Tooltip: Open a ChatGPT window inside Revit, without switching to a browser.

Ask about a Revit workflow, a code question, or a design problem and keep the answer next to the model you are working in. Nothing in the model is touched.

Check Error Log

Tooltip: Open the EnneadTab error log in your browser to see reported bugs and their status.

Every error EnneadTab catches is filed here. Use it to check whether the problem you just hit is already known, to see what has been fixed, or to add detail to a report you sent in.

Display Revit Warning History

Tooltip: Show how the warning count in a model has moved over time.

EnneadTab quietly records the warning list for your models, so this button can replay that history as a graph: whether warnings are creeping up, when a cleanup actually landed, and which ones came back.

Usage:

1. Choose the graph alone, or the graph plus the full warning detail
2. Pick the models to report on
3. Review the history in the output window

Documentation Hint

Tooltip: Quickly print all the [Did you know] documentations.

EnneadTab Setting

Tooltip: Personalize how EnneadTab looks and behaves, from one settings window.

Choose which tabs and extensions show up on the ribbon, switch between the Lite and Pro tool sets, set colors and notification preferences, and decide how chatty the duck gets. Your choices are remembered for next time.

Features:

- Show or hide individual EnneadTab tabs and extensions
- Toggle between the Lite and Pro tool sets
- Sound, notification, and duck behavior preferences

MiniBank

Tooltip: Check your EA coin balance and where you sit on the office leaderboard.

Quacks add up as you use EnneadTab tools, clear model warnings, and wait your turn in the sync queue. The window shows your balance, your standing and your recent transactions; nothing in the model changes.

Open Ecosystem Folder

Tooltip: Jump to the ecosystem folder where you can inspect all the magic.

Reload EnneadTab

Tooltip: Reload entire UI so can get newer buttons.....

Remote Fix Code

Tooltip: Emergency code fix tool for remote debugging and editing using VS Code Dev

Soft Reload

Tooltip: Just download the new repo and unzip. This will not reload the Reevit for UI change.

Tell Me Version

Tooltip: Show which EnneadTab version you are on and when it last updated successfully.

Worth checking when you file a bug, when you want to confirm a fix has reached your machine, or when you and a teammate need to be sure you are running the same build.

Unit Test

Tooltip: Run a self-check on the core EnneadTab services and report anything broken.

Reach for this when EnneadTab starts behaving strangely after an update. It exercises the shared services every other tool leans on and prints a pass or fail for each one, which is worth pasting into a bug report.

AI Render

Tooltip: Render the current view through Ennead's in-house AI style library.

Queue several renders at once and carry on modeling while they run. Your gallery follows you between machines, so a render you start at one desk can be picked up at another.

Features:

- Style references pulled straight from the Ennead library
- Prompt helpers from ennead-ai.com to sharpen a description
- Queue multiple views and collect the results in one gallery

AI Translate

Tooltip: Translate sheet and view names into another language, with a review step first.

Covers 15 languages including Chinese, Japanese, Korean, Spanish, French, German, Arabic and Hindi, and leans on each country's official AEC vocabulary so the wording reads the way a local consultant would write it, not the way a generic translator would.

Usage:

1. Pick the sheets or views to translate and the target language
2. Review the proposed names side by side with the originals
3. Approve, and only the names you accepted are written back

Align H. Curtain Grid To Detail Lines/Levels(Elevation)

Tooltip: Snap horizontal curtain grids onto the detail lines or levels that cross them.

Draw your intended grid heights as detail lines, or just use the levels already in the elevation, and the curtain grids move to match. Beats nudging each grid line by hand when a facade rhythm changes.

Usage:

1. Open an elevation view of the curtain wall
2. Run the button and pick the detail lines or levels to align to
3. Pick the curtain grids that should move

Align V. Curtain Grid To Detail Lines/Grids(Plan)

Tooltip: Snap vertical curtain grids onto the detail lines or column grids that cross them.

Draw your intended mullion positions as detail lines, or just use the column grids already in the plan, and the curtain grids move to match. Beats nudging each grid line by hand when a facade rhythm changes.

Usage:

1. Open a plan view showing the curtain wall
2. Run the button and pick the detail lines or grids to align to
3. Pick the curtain grids that should move

Apply Panel Radius

Tooltip: Push the host curtain wall's radius into the panels sitting on it.

Curved curtain walls are found for you and their radius is written into a parameter on every panel, so panel families bend to match the wall instead of being dialed in by hand one at a time. The facade stays consistent as the curvature changes.

Usage:

1. Run the button to open the window
2. Pick the panel type and the parameter that should receive the radius
3. Apply, then check the count of updated panels

Area2Mass

Tooltip: Turn area boundaries into solid mass families and place them back in the project.

Pick an area scheme and every area becomes its own loadable mass, extruded up to the next level above and dropped exactly where the original area sits. Handy for zoning diagrams, gross-area studies and quick massing pulled straight from your area plans.

Features:

- Choose which area scheme to convert
- Each mass lands in place, so no repositioning is needed
- Masses are ordinary families you can schedule, filter and color

Batch Cut Elements

Tooltip: Powerful batch cutting utility for curtain wall systems.

This tool enables efficient creation of void cuts across multiple curtain panels.

Features:

- Batch process curtain walls or individual panels
- Support for multiple selection methods
- Intelligent void detection and validation
- Transaction-safe operations with error handling

Usage:

1. Select curtain walls or panels
2. Choose void geometry
3. Apply cuts across all selected elements

Color-Code Design Option

Tooltip: Color-code every element by the design option it belongs to, across the views you pick.

At a glance you can see which option each element lives in, so nothing gets reviewed or presented under the wrong assumption. Ideal for design reviews and pin-ups where several alternatives are in play at once.

Features:

- Each design option gets its own color
- Applies to as many views as you select in one go
- Colors are a view override, so the model itself is untouched

Detail Line By Excel

Tooltip: Draw detail lines from survey coordinates listed in an Excel file.

Point data from the spreadsheet is placed at exact coordinates and chained into detail lines, then bundled into a group so the whole run can be moved as one piece. Built for property lines, site boundaries and any linework that has to land on surveyed points.

Usage:

1. Prepare an Excel file with the survey coordinates
2. Run the button and point it at that file
3. The lines are drawn in the current view as a single group

Dim Text Helper

Tooltip: Add standard dimension text such as FOG, EOS or FTF to the dimensions you select.

A small floating window stays open while you work, so you can keep selecting dimensions and stamping text on them without reopening anything. Choose where the text sits relative to the dimension value, and add your own phrases to the list for next time.

Features:

- Common annotations ready to click, plus your own custom entries
- Control whether the text goes above, below, before or after the value
- Your custom entries are remembered between sessions
- Window stays open so you can work through many dimensions in a row

Disallow Wall End Joins

Tooltip: Disallow end joins on every wall of the wall types you choose.

Walls of the selected types stop auto-joining at their endpoints, which keeps stacked or layered wall assemblies from cleaning up into each other and ruining the intended graphic. Runs as a single undo step.

Features:

- Pick one or many wall types and treat every wall of that type at once
- Both ends of each wall are handled
- Summary of how many walls were changed

Explode Axon

Tooltip: Build an exploded axon by lifting each level apart in a 3D view.

Elements are grouped by the level they sit on and pulled upward by a spacing you choose, so the building reads as separated floor plates. The displacement lives in the view only, so the model geometry never moves and you can reset or redo it at any time.

Usage:

1. Run the button from a 3D view
2. Pick the categories you want to explode
3. Enter the spacing in feet between levels

Finish Floor by Room

Tooltip: Create finish floors from picked Rooms.

Pick rooms in the model, choose a floor type (ranked by your recent usage, then alphabetical), set a level offset (mm and inch are tied), then create one finish floor per room. All floors land in a single undo step.

- While picking, Rooms and Room Tags are temporarily isolated in the active view so they are easy to select; the view is restored afterwards.
- Uses each room's own Level; the offset is written to 'Height Offset From Level'.
- Only the outer room boundary is used (solid finish floor, inner loops ignored).
- Rooms already given a finish floor by this tool are skipped (no duplicates).
- Rooms with no boundary / no level / bad geometry are skipped and reported.

GetInspired

Tooltip: Open e.AI rendering website for enhancing and refining your renders!

This tool opens the e.AI web application (<https://enneadtab.com/rendering/home>) that helps you:

- Polish and enhance render outputs
- Apply post-processing effects
- Refine render quality and appearance
- Streamline your rendering workflow

Perfect for visualization specialists looking to take their renders to the next level.

Join Selected Elements

Tooltip: Join horizontal elements to vertical ones in bulk, such as floors into columns.

Instead of picking pairs by hand, choose the two categories and every overlapping pair in the model is joined in one pass. Cleans up the slab-to-column edges that otherwise show through in sections and elevations.

Usage:

1. Pick the horizontal category, for example Floors or Ceilings
2. Pick the vertical category, for example Columns or Structural Columns
3. Review the count of joins made in the output window

MCP Server

Tooltip: Turn the EnneadTab AI bridge for this Revit session on or off.

While it is on, an AI assistant can look at the open model and carry out changes for you in this session. The button shows the current state, so one click starts the bridge and the next click shuts it down again.

Features:

- Only the Revit session you started it from is exposed
- The bridge stops as soon as you toggle it off or close Revit
- pyRevit Routes must be enabled first, and you are told if it is not

Make Template From Current View

Tooltip: Save the current view's settings as a view template and apply it everywhere it belongs.

Unlike the built-in Revit command, this also repairs a template that was created under the wrong view type, which is what makes templates show up in the wrong group in the browser. Every view that used the old template is moved onto the new one and the old template is removed, so you are not left with duplicates.

Usage:

1. Set up the view exactly how you want the template to look
2. Run the button and name the template
3. Reuse the existing name to replace the template the view is already on

NYU Export CAD Layer Mapping

Tooltip: Apply NYU CAD Layer Standards to DWG Export Settings.

This tool maps Revit categories to NYU standard layer names and colors.

All subcategories will use the parent category's layer settings.

Open Doc(s) Silently

Tooltip: Open many Revit files in one go without stopping for warning dialogs.

Warnings that would normally halt the queue are answered for you, so a batch of models can open unattended while you do something else. A summary at the end says which files opened and which did not.

Features:

- Optional audit on open
- Optional detached opening with no worksets loaded
- Summary report of every file in the batch

Orient Scopebox

Tooltip: Rotate selected scope boxes until they line up with a model line you pick.

Draw a model line along the direction the building actually runs, and each scope box is turned until its edges are parallel to it. Odd starting angles are handled, and it usually settles within a few passes.

Usage:

1. Draw or pick a model line to align to
2. Pick the scope boxes to orient

Pim Number Fixer

Tooltip:

Pim Number Fixer

This tool allows users to batch rename DWG and PDF files by updating or inserting a PIM number into their filenames. It provides a simple UI to select files, preview the new filenames, and perform the renaming operation. The tool also remembers the last used PIM number for convenience.

Typical use cases:

- Standardizing file naming conventions for project documentation.
- Quickly updating PIM numbers in multiple files after project changes.

Note: This tool operates on the file system and does not require an open Revit document.

Project Config

Tooltip: Open the Project Config window and pick the project setup task you want to run.

One modeless window gathers the healthcare project tools (design outline, project initialization, DGSF chart, color palette) together with the generic project-data setup/edit actions, so you do not have to hunt for separate buttons. The window stays open after you trigger an action, so you can run several in a row.

Features:

- Read the Ennead healthcare design outline
- Initialize a new healthcare project
- Edit or open the project data setup
- Update the detailed DGSF chart
- Refresh the department color palette from an Excel file

Random Deselect

Tooltip: Random deselection tool for Revit elements.

This tool allows you to randomly deselect a portion of your currently selected elements. Perfect for when you have too many elements selected and want to reduce the selection to a manageable subset for further operations.

Features:

- Uses PyRevit input slider to control percentage of elements to keep
- Random selection ensures unbiased element reduction
- Preserves original selection order for consistency
- Safe operation with proper error handling

Usage:

1. Select elements you want to work with
2. Run this tool
3. Use the slider to set percentage of elements to keep (0-100%)
4. Confirm to apply random deselection

Reset Join/Cut

Tooltip: Strip every join and cut relationship from the elements you have selected.

When geometry is fighting itself and you cannot tell which element is cutting or joining which, this gives you a clean slate to rebuild from. A report lists each relationship that was found and removed.

Features:

- Handles both cutting and joining relationships
- Reports what was undone, element by element
- One undo step, so you can put it all back if needed

See You Again

Tooltip: Smart session scheduler that prepares your Revit environment for your next work session.

This time-saving utility allows you to:

- Schedule your current Revit files to reopen automatically
- Choose when they reopen: in minutes, tomorrow morning, or next Monday
- Skip the lengthy file loading process when you return to work
- Maintain your exact workspace configuration between sessions

Perfect for teams working with large projects that take significant time to open each day.

Set FilledRegion Border Style

Tooltip: Set the border line style on all the filled regions you have selected.

Brings a whole drawing's hatches onto the same graphic standard in one move instead of editing each region's boundary. Works on regions nested inside groups too, as long as you tab-select them.

Usage:

1. Select the filled regions, using Tab to reach any inside a group
2. Run the button and pick the line style you want on their borders

Super Renamer

Tooltip: Rename views, sheets and families in bulk from one window.

Keeps naming consistent across the project without clicking through the project browser one item at a time.

Features:

- Add or strip a prefix on the views you select
- Push view and sheet names to uppercase
- Rebuild view names from their detail number and sheet number
- Rename families directly from the same window

Sync All Open Proj and Close

Tooltip: Sync every open model with central, then close them, leaving Revit running.

Use it when you are switching projects or stepping away: all your work reaches the central files and the documents are closed behind you, but Revit stays open so you can start something else.

Sync All Open Proj

Tooltip: Sync every open model with central in one click and keep working.

All open documents are synchronized and left open, so your changes reach the team without interrupting what you are doing. Worth running regularly through the day instead of hoarding a whole afternoon of work.

Sync and Quit

Tooltip: Sync every open model with central, close them all, and shut Revit down.

The one-click end of the day: nothing left open, nothing left unsynced. Revit closes itself once the last model has finished syncing, so you can walk away.

Tag Aligner

Tooltip: Line up scattered tags horizontally or vertically against one reference tag.

A small floating window stays open while you work, so you can keep selecting groups of tags and straightening them without reopening anything. Turns a messy sheet of hand-dragged tags into clean, readable annotation.

Usage:

1. Select the tags you want to line up
2. Click align horizontally or vertically in the floating window
3. Repeat on the next group; the window stays open

Toggle Contents

Tooltip: Pin, hide and tidy whole categories of content across many views from one window.

Everything you normally toggle view by view is gathered in a single floating panel, so a sheet set can be cleaned up or locked down in a couple of clicks instead of a long crawl through the project browser.

Features:

- Pin or unpin dimensions, keynote tags, viewports and title blocks
- Hide or show categories on the sheets you pick, permanently or as a temporary view state
- Turn grid and level bubble heads on or off
- Hide viewport borders for a clean pin-up

BIM Client

Tooltip: Print a health report for the EnneadTab environment inside this Revit session.

Use it when something is misbehaving and you want to know whether the problem is your model or your setup. Nothing in the model is read or changed; the report simply appears in the output window and can be pasted straight into a support message.

Features:

- Names the active document and how many elements it holds
- Confirms the EnneadTab library and the Revit connection are alive
- Checks that the AI service responds
- Flags any missing component instead of failing quietly

Open App Store

Tooltip: Open the EnneadTab App Store to browse and install extra tools.

One place to discover what the office has built, add what you need, and keep what you already have up to date.

Ownership Inspect

Tooltip: See who created, owns and last changed every element in a workshared model.

One scan builds a searchable table so you know exactly whom to ask before you touch something, and which view an annotation actually lives in.

Features:

- Search bar, category filter and an owned-by-me-only toggle
- Separate tab listing views and their owners
- Select, zoom to, or open the host view straight from the table
- Read-only: nothing in the model is changed

Pick Absolute Similar

Tooltip: Find elements with matching parameters by comparing parameter values across elements.

Place Views On Sheets

Tooltip: Catch every newly created view and get it named, templated and onto a sheet.

A floating window lists the views that appeared since you started, so nothing gets left unnamed or unplaced. Keep it open while you work and finish each view as it shows up.

Features:

- Rename a view, or accept the suggested name based on its sheet
- Drop the view onto a sheet from the same window
- Assign a scope box and a view template while you are there
- Window stays open so Revit is still usable behind it

Prefilter Selection

Tooltip: Limit what a window selection can pick up, so a crowded view stops fighting you.

Choose the categories you care about first, then drag a window and only those categories are caught. Saves the usual dance of selecting everything and then filtering it back down.

Features:

- Turn on as many categories at once as you need
- Works with normal window and crossing selection
- Setting stays active until you clear it

Search Command

Tooltip: Find any Revit or EnneadTab command by typing what you want to do.

Search by name or by what a tool does, and the best matches come back ranked. Faster than hunting through ribbon panels for a button whose exact name you cannot recall.

Features:

- Covers both EnneadTab tools and native Revit commands
- Shows where on the ribbon each match lives
- Run the tool straight from the results
- Reads out the tool's description and links to further help

Toggle Warnings

Tooltip: Show warnings in the active view.

What Happened?

Tooltip: Find out who made, who last edited and who owns whatever you have selected.

Answers the question you ask whenever something looks wrong: who did this, and can I touch it. Also reports the same for the view you are currently in.

Features:

- Creator, last editor and current owner for each selected element
- Same information for the active view
- Read-only: nothing in the model is changed

Family Browser

Tooltip: Browse and place digital assets from EnneadTab-Library directly into the active document.

Disclaimer: EnneadTab only helps you find and load the asset, but is not participating in the creation and maintenance of the library content.

MetaData Exporter

Tooltip: Read every family in the library and record its details for later search.

Builds the data the Ennead Library browser uses, so families can be found by their type and view information instead of by filename alone. Run it after adding or changing families in the library.

Features:

- Covers every family in the library in one pass
- Existing records are refreshed, not duplicated

How to Use Ennead Library

Tooltip: Explains how to load a family from the Ennead Library into your model.

Click a family icon in the library to load it. Families saved in an older Revit version are upgraded for you as they load, so they are ready to use straight away.

Tailor Scripts Information

This documentation excludes EnneadTab Tailor scripts from the main content.

222 tailor-related scripts were skipped for **Revit**.

Tailor scripts are project-specific customizations and are not included in the general documentation.
